Batch: E3

Experiment No: 8a

AIM: To test and deploy production ready Flutter App on Android platform

THEORY:**Build and release an Android app**

During a typical development cycle, you test an app using `flutter run` at the command line, or by using the **Run** and **Debug** options in your IDE. By default, Flutter builds a *debug* version of your app.

To [publish an app to the Google Play Store](#), you need to prepare a *release* version of your app. Before publishing, you might want to put some finishing touches on your app. This may covers the following topics:

- [Adding a launcher icon](#)
- [Enabling Material Components](#)
- [Signing the app](#)
- [Shrinking your code with R8](#)
- [Enabling multidex support](#)
- [Reviewing the app manifest](#)
- [Reviewing the build configuration](#)
- [Building the app for release](#)
- [Publishing to the Google Play Store](#)
- [Updating the app's version number](#)
- [Android release FAQ](#)

Note: Throughout this manual, `[project]` refers to the directory that your application is in. While following these instructions, substitute `[project]` with your app's directory.

Adding a launcher icon

When a new Flutter app is created, it has a default launcher icon. To customize this icon, you might want to check out the [flutter_launcher_icons](#) package.

Alternatively, you can do it manually using the following steps:

1. Review the [Material Design product icons](#) guidelines for icon design.
2. In the `[project]/android/app/src/main/res/` directory, place your icon files in folders named using [configuration qualifiers](#). The default `mipmap-` folders demonstrate the correct naming convention.
3. In `AndroidManifest.xml`, update the `application` tag's `android:icon` attribute to reference icons from the previous step (for example, `<application android:icon="@mipmap/ic_launcher" ...>`).
4. To verify that the icon has been replaced, run your app and inspect the app icon in the Launcher.

Enabling Material Components

If your app uses [Platform Views](#), you may want to enable Material Components by following the steps described in the [Getting Started guide for Android](#).

For example:

1. Add the dependency on Android's Material in `<my-app>/android/app/build.gradle`:

```
dependencies {
    implementation 'com.google.android.material:material:<version>'
}
```

To find out the latest version, visit [Google Maven](#).

```
dependencies {
    implementation "org.jetbrains.kotlin:kotlin-stdlib-jdk7:$kotlin_version"
    implementation "com.google.android.material:material:1.9.0-alpha02"
}
```

1. Set the light theme in <my-app>/android/app/src/main/res/values/styles.xml:

```
-<style name="NormalTheme" parent="@android:style/Theme.Light.NoTitleBar">
+<style name="NormalTheme" parent="Theme.MaterialComponents.Light.NoActionBar">
```

```
styles.xml x
14 |     This Theme is only used starting with V2 of Flutter's Android embedding. -->
15 |
16 |     <!-- <style name="NormalTheme" parent="@android:style/Theme.Light.NoTitleBar">-->
17 |     <style name="NormalTheme" parent="Theme.MaterialComponents.Light.NoActionBar">
18 |         <item name="android:windowBackground">?android:colorBackground</item>
19 |     </style>
20 </resources>
21
```

2. Set the dark theme in <my-app>/android/app/src/main/res/values-night/styles.xml

```
-<style name="NormalTheme" parent="@android:style/Theme.Black.NoTitleBar">
+<style name="NormalTheme" parent="Theme.MaterialComponents.DayNight.NoActionBar">
```

```
styles.xml x
14 |     This Theme is only used starting with V2 of Flutter's Android embedding. -->
15 |
16 |     <!--<style name="NormalTheme" parent="@android:style/Theme.Black.NoTitleBar">-->
17 |     <style name="NormalTheme" parent="Theme.MaterialComponents.DayNight.NoActionBar">
18 |         <item name="android:windowBackground">?android:colorBackground</item>
19 |     </style>
20 </resources>
21
```

Signing the app

To publish on the Play Store, you need to give your app a digital signature. Use the following instructions to sign your app.

On Android, there are two signing keys: **deployment and upload**. The end-users download the .apk signed with the ‘deployment key’. An ‘upload key’ is used to authenticate the .aab / .apk uploaded by developers onto the Play Store and is re-signed with the deployment key once in the Play Store.

- It’s highly recommended to use the automatic cloud managed signing for the deployment key. For more information, see the [official Play Store documentation](#).

Create an upload keystore

If you have an existing keystore, skip to the next step. If not, create one by either:

- Following the [Android Studio key generation steps](#)
- Running the following at the command line:

On Mac/Linux, use the following command:

```
keytool -genkey -v -keystore ~/upload-keystore.jks -keyalg RSA -keysize 2048 -validity 10000 -alias upload
```

On Windows, use the following command:

```
keytool -genkey -v -keystore c:\Users\USER_NAME\upload-keystore.jks -storetype JKS -keyalg RSA -keysize 2048 -validity 10000 -alias upload
```

This command stores the [upload-keystore.jks](#) file in your home directory. If you want to store it elsewhere, change the argument you pass to the [-keystore](#) parameter. **However, keep the keystore file private; don't check it into public source control!**

```
PS C:\Users\exam\Desktop\120A3051\my_app> keytool -genkey -v -keystore c:\Users\exam\upload-keystore.jks -storetype JKS -keyalg RSA -keysize 2048 -validity 10000 -alias upload
Enter keystore password:
Re-enter new password:
What is your first and last name?
[Unknown]: Shreya Idate
What is the name of your organizational unit?
[Unknown]: SIES GST
What is the name of your organization?
[Unknown]: SIES
What is the name of your City or Locality?
[Unknown]: Navi Mumbai
What is the name of your State or Province?
[Unknown]: Maharashtra
What is the two-letter country code for this unit?
[Unknown]: MH
[no]: yes

Generating 2,048 bit RSA key pair and self-signed certificate (SHA256withRSA) with a validity of 10,000 days
    for: CN=Shreya Idate, OU=SIES GST, O=SIES, L=Navi Mumbai, ST=Maharashtra, C=MH
Enter key password for <upload>
    (RETURN if same as keystore password):
Re-enter new password:
[Storing c:\Users\exam\upload-keystore.jks]

Warning:
The JKS keystore uses a proprietary format. It is recommended to migrate to PKCS12 which is an industry standard format using "keytool -importkeystore -srckeystore c:\Users\exam\upload-keystore.jks -destkeystore c:\Users\exam\upload-keystore.jks -deststoretype pkcs12".
```

```
PS C:\Users\exam\Desktop\120A3051\my_app> keytool -importkeystore -srckeystore c:\Users\exam\upload-keystore.jks -destkeystore c:\Users\exam\upload-keystore.jks -deststoretype pkcs12
Enter source keystore password:
Entry for alias upload successfully imported.
Import command completed: 1 entries successfully imported, 0 entries failed or cancelled

Warning:
Migrated "c:\Users\exam\upload-keystore.jks" to PKCS12. The JKS keystore is backed up as "c:\Users\exam\upload-keystore.jks.old".
```

Note:

- The [keytool](#) command might not be in your path—it's part of Java, which is installed as part of Android Studio. For the concrete path, run [flutter doctor -v](#) and locate the path printed after 'Java binary at:' then use that fully qualified path replacing [java](#) (at the end) with [keytool](#). If your path includes space-separated names, such as [Program Files](#), use platform-appropriate notation for the names. For example, on Mac/Linux use [Program\ Files](#), and on Windows use ["Program Files"](#).
- The [-storetype JKS](#) tag is only required for Java 9 or newer. As of the Java 9 release, the keystore type defaults to PKS12.

```
C:\WINDOWS\system32\cmd.exe
Microsoft Windows [Version 10.0.19045.2486]
(c) Microsoft Corporation. All rights reserved.

C:\Users\exam>java --version
openjdk 11.0.12 2021-07-20
OpenJDK Runtime Environment Microsoft-25199 (build 11.0.12+7)
OpenJDK 64-Bit Server VM Microsoft-25199 (build 11.0.12+7, mixed mode)

C:\Users\exam>
```

Reference the keystore from the app

Create a file named [\[project\]/android/key.properties](#) that contains a reference to your keystore:

```
storePassword=<password from previous step>
keyPassword=<password from previous step>
keyAlias=upload
storeFile=<location of the key store file, such as /Users/<user name>/upload-keystore.jks>
```

```
key.properties X
android > key.properties
1  storePassword=shreya@123
2  keyPassword=shreya@123
3  keyAlias=upload
4  storeFile=c:/Users/exam/upload-keystore.jks
```

Configure signing in gradle

Configure gradle to use your upload key when building your app in release mode by editing the [\[project\]/android/app/build.gradle](#) file.

1. Add the keystore information from your properties file before the `android` block:

```
def keystoreProperties = new Properties()
def keystorePropertiesFile = rootProject.file('key.properties')
if (keystorePropertiesFile.exists()) {
    keystoreProperties.load(new FileInputStream(keystorePropertiesFile))
}

android { ...
}
```

Load the `key.properties` file into the `keystoreProperties` object.

```
build.gradle X
android > app > build.gradle > keystoreProperties
28
29  def keystoreProperties = new Properties()
30  def keystorePropertiesFile = rootProject.file('key.properties')
31  if (keystorePropertiesFile.exists()) {
32      keystoreProperties.load(new FileInputStream(keystorePropertiesFile))
33  }
34
```

2. Find the `buildTypes` block:

```
buildTypes {
release {
// TODO: Add your own signing config for the release build.
// Signing with the debug keys for now,
// so `flutter run --release` works. signingConfig signingConfigs.debug
} }
```

And replace it with the following signing configuration info:

```
signingConfigs {  
    release {  
        keyAlias keystoreProperties['keyAlias']  
        keyPassword keystoreProperties['keyPassword']  
        storeFile keystoreProperties['storeFile'] ? file(keystoreProperties['storeFile']) : null  
        storePassword keystoreProperties['storePassword']  
    }  
}  
buildTypes {  
    release {  
        signingConfig signingConfigs.release  
    }  
}
```

```
android > app > build.gradle > ...  
63     signingConfigs {  
64         release {  
65             keyAlias keystoreProperties['keyAlias']  
66             keyPassword keystoreProperties['keyPassword']  
67             storeFile keystoreProperties['storeFile'] ? file(keystoreProperties['storeFile']) : null  
68             storePassword keystoreProperties['storePassword']  
69         }  
70     }  
71     buildTypes {  
72         release {  
73             // TODO: Add your own signing config for the release build.  
             // Signing with the debug keys for now, so `flutter run --release` works.  
             signingConfig signingConfigs.release  
77         }  
78     }  
79 }
```

Release builds of your app will now be signed automatically.

Shrinking your code with R8

[R8](#) is the new code shrinker from Google, and it's enabled by default when you build a release APK or AAB. To disable R8, pass the `--no-shrink` flag to `flutter build apk` or `flutter build appbundle`.

Note: Obfuscation and minification can considerably extend compile time of the Android application.

Enabling multidex support

When writing large apps or making use of large plugins, you may encounter Android's dex limit of 64k methods when targeting a minimum API of 20 or below. This may also be encountered when running debug versions of your app via `flutter run` that does not have shrinking enabled.

Flutter tool supports easily enabling multidex. The simplest way is to opt into multidex support when prompted. The tool detects multidex build errors and will ask before making changes to your Android project. Opting in allows Flutter to automatically depend on `androidx.multidex:multidex` and use a generated `FlutterMultiDexApplication` as the project's application.

Note: Multidex support is natively included when targeting min sdk 21+.

Reviewing the app manifest

Review the default [App Manifest](#) file, `AndroidManifest.xml`, located in `[project]/android/app/src/main` and verify that the values are correct, especially the following:

application

Edit the `android:label` in the `application` tag to reflect the final name of the app.

uses-permission

Add the `android.permission.INTERNET` permission if your application code needs Internet access. The standard template does not include this tag but allows Internet access during development to enable communication between Flutter tools and a running app.

Reviewing the build configuration:

Review the default [Gradle build file](#) (`build.gradle`) located in `[project]/android/app` and the `local.properties` file located in `[project]/android` to verify the values are correct, especially the following values in the `defaultConfig` block:

In `build.gradle` file

applicationId

Specify the final, unique (Application Id) [appid](#)

compileSdkVersion

Specify the API level Gradle should use to compile your app. For more information, see the module-level build section in the [Gradle build file](#).

buildToolsVersion

If you're using Android plugin for Gradle 3.0.0 or higher, your project automatically uses the default version of the build tools that the plugin specifies. Alternatively, you can specify a version of the build tools.

In `local.properties` file

flutter.versionCode & flutter.versionName

Specify the internal app version number, and the version number display string. You can do this by setting the `version` property in the `pubspec.yaml` file. For more information, see the version information guidance in the [versions documentation](#).

flutter.minSdkVersion & flutter.targetSdkVersion

Specify the minimum API level and the target API level on which the app is designed to run. For more information, see the API level section in the [versions documentation](#).

Building the app for release

You have two possible release formats when publishing to the Play Store.

- AAB (Android App bundle) - preferred
- APK

Build an app bundle

This section describes how to build a release app bundle. If you completed the signing steps, the app bundle will be signed. At this point, you might consider [obfuscating your Dart code](#) to make it more difficult to reverse engineer. Obfuscating your code involves adding a couple flags to your build command, and maintaining additional files to deobfuscate stack traces.

From the command line:

1. Enter `cd [project]`
 2. Run `flutter build appbundle` (Running `flutter build` defaults to a release build.)
- The release bundle for your app is created at `[project]/build/app/outputs/bundle/release/app.aab`.

By default, the app bundle contains your Dart code and the Flutter runtime compiled for [armeabi-v7a](#) (ARM 32-bit), [arm64-v8a](#) (ARM 64-bit), and [x86-64](#) (x86 64-bit).

```
PS C:\Users\exam\Desktop\120A3051\my_app> flutter build appbundle
Building with Flutter multidex support enabled.
Font asset "MaterialIcons-Regular.otf" was tree-shaken, reducing it from 1645184 to 1284 bytes (99.9% reduction). Tree-shaking can be disabled by providing the --no-tree-shake-icons flag when building your app.
Running Gradle task 'bundleRelease'...                                                 55.7s
✓ Built build/app/outputs/bundle/release/app-release.aab (19.2MB).
PS C:\Users\exam\Desktop\120A3051\my_app> 
```

Test the app bundle

An app bundle can be tested in multiple ways—this section describes two.

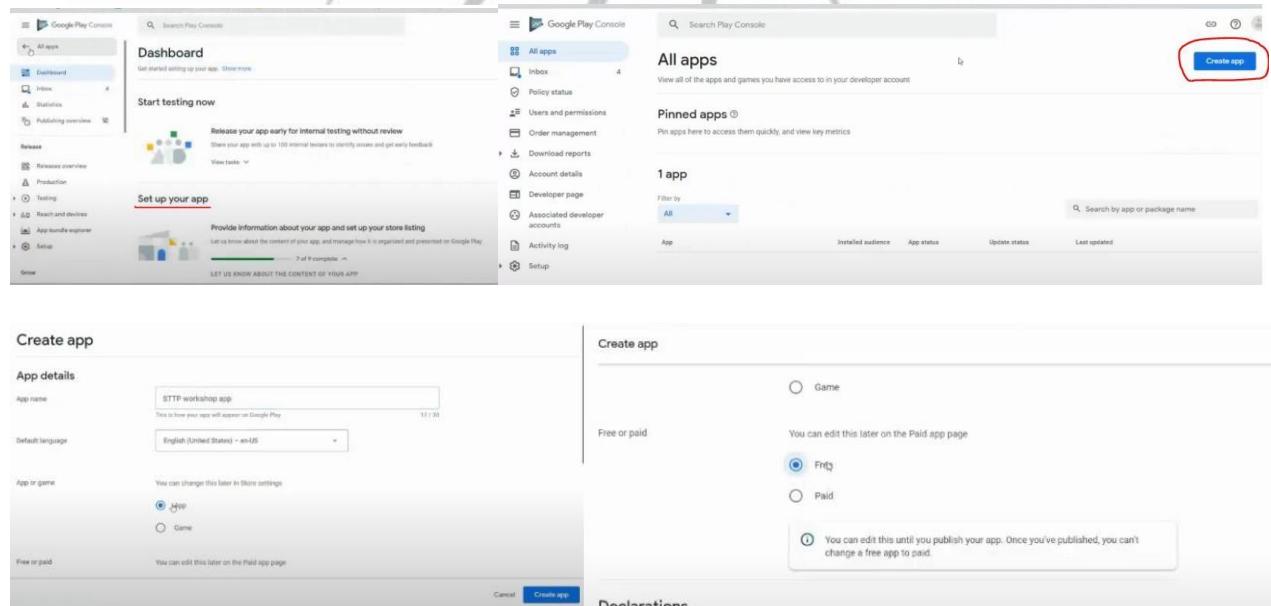

Offline using the bundle tool

1. If you haven't done so already, download [bundletool](#) from the [GitHub repository](#).
2. [Generate a set of APKs](#) from your app bundle.
3. [Deploy the APKs](#) to connected devices.

Online using Google Play

Upload your bundle to Google Play to test it. You can use the internal test track, or the alpha or beta channels to test the bundle before releasing it in production.

1. Follow [these steps to upload your bundle](#) to the Play Store.

If parts of your app are restricted based on login credentials, memberships, location, or other forms of authentication, provide instructions on how to access them. Make sure this information is kept up to date.

Google may use this information to review your app. It won't be shared, or used for any other reason. Learn more.

Build an APK

Although app bundles are preferred over APKs, there are stores that don't yet support app bundles. In this case, build a release APK for each target ABI (Application Binary Interface).

If you completed the signing steps, the APK will be signed. At this point, you might consider [obfuscating your Dart code](#) to make it more difficult to reverse engineer. Obfuscating your code involves adding a couple flags to your build command.

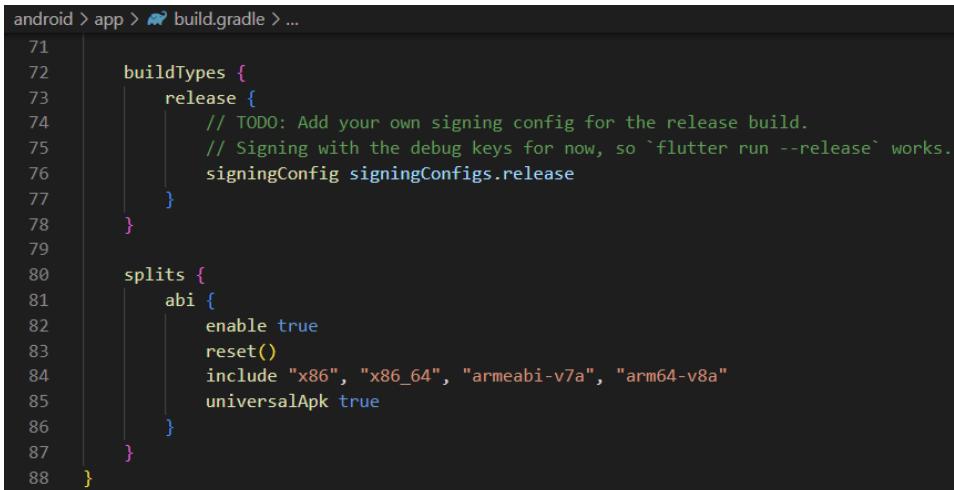

From the command line:

1. Enter `cd [project]`
2. Run `flutter build apk --split-per-abi`
(The `flutter build` command defaults to `--release`.) This command results in three APK files:

- `[project]/build/app/outputs/apk/release/app-armeabi-v7a-release.apk`
- `[project]/build/app/outputs/apk/release/app-arm64-v8a-release.apk`
- `[project]/build/app/outputs/apk/release/app-x86_64-release.apk`

Removing the `--split-per-abi` flag results in a fat APK that contains your code compiled for *all* the target ABIs. Such APKs are larger in size than their split counterparts, causing the user to download native binaries that are not applicable to their device's architecture.

```
PS C:\Users\exam\Desktop\120A3051\my_app> flutter build apk --split-per-abi
Building with Flutter multidex support enabled.
Running Gradle task 'assembleRelease'...
17.9s
✓ Built build/app/outputs/flutter-apk/app-armeabi-v7a-release.apk (8.1MB).
✓ Built build/app/outputs/flutter-apk/app-arm64-v8a-release.apk (8.6MB).
✓ Built build/app/outputs/flutter-apk/app-x86_64-release.apk (8.7MB).
PS C:\Users\exam\Desktop\120A3051\my_app>
```

```
71
72     buildTypes {
73         release {
74             // TODO: Add your own signing config for the release build.
75             // Signing with the debug keys for now, so `flutter run --release` works.
76             signingConfig signingConfigs.release
77         }
78     }
79
80     splits {
81         abi {
82             enable true
83             reset()
84             include "x86", "x86_64", "armeabi-v7a", "arm64-v8a"
85             universalApk true
86         }
87     }
88 }
```

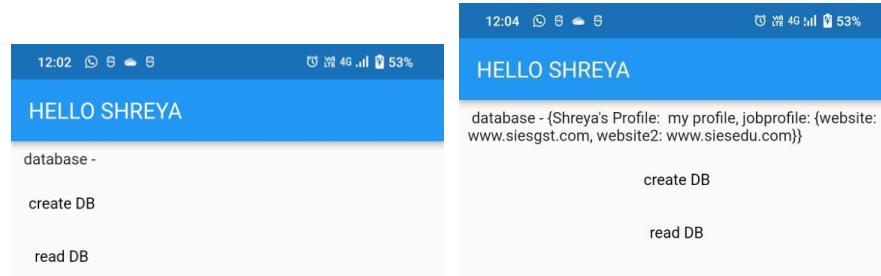

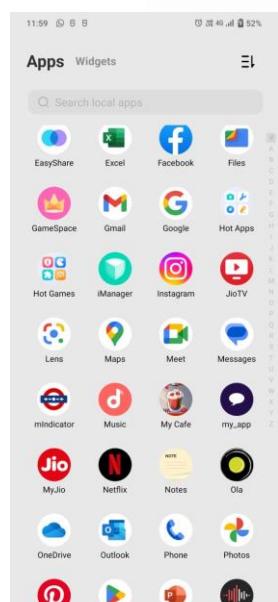

Install an APK on a device

Follow these steps to install the APK on a connected Android

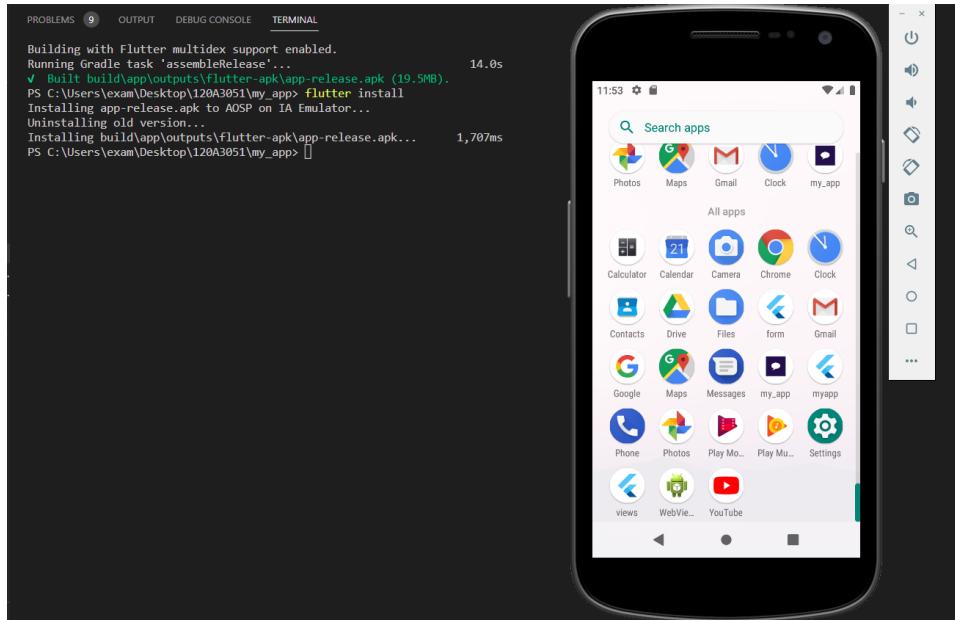

device. From the command line:

1. Connect your Android device to your computer with a USB cable.
2. Enter `cd [project]`.
3. Run `flutter install`.

```
PS C:\Users\exam\Desktop\120A3051\my_app> flutter install
Installing app-release.apk to V2126...
Installing build/app/outputs/flutter-apk/app-release.apk...        4.2s
PS C:\Users\exam\Desktop\120A3051\my_app>
```

To install it on emulator, create an AVD with an x86 image from Android Studio:

```
splits
{
  // Configures multiple APKs based on ABI.
  abi {
    // Enables building multiple APKs per ABI.
    enable true
    // By default all ABIs are included, so use reset() and include to specify that we only
    // want APKs for x86, armeabi-v7a, and mips.
    reset()
    // Specifies a list of ABIs that Gradle should create APKs for.
    include "x86", "x86_64", "armeabi-v7a", "arm64-v8a"
    // Specifies that we want to also generate a universal APK that includes all ABIs.
    universalApk true
  }
}
```

Conclusion: Successfully tested and deployed production ready Flutter App on Android platform
